Dosa and Drinks

Part 1: Business Identification and Template Selection

Business Name: Dosa and Drinks

Business Description:
Dosa and Drinks is a fictional dosa restaurant located in Minneapolis. This restaurant focuses on serving a wide variety of dosas, which are one of my favorite foods. I noticed that it can be hard to find a dosa place in Minneapolis with authentic flavors and diverse options, so this restaurant aims to fill that gap. Dosa and drinks will offer classic and modern dosa varieties, along with drinks like fresh juices, lassis, and coffees to create a complete experience. The goal is to provide a casual, comfortable place where people can enjoy high-quality South Indian food.

Template Selected:
For the website design, I selected the Cafe template provided. This template has a cozy and inviting style that works well for representing a restaurant. It can be easily customized to show menu items, drinks, contact information, and other important details for the dosa restaurant.

Part 2: AWS Service Selection

For my Dosa and Drinks website, I chose services that will make the site fast, secure, and easy to access, without adding anything extra. Since this is a simple static website (just HTML, CSS, and maybe images), I don't need any heavy or complicated services. Here's what I picked and why:

1. Amazon S3 (Simple Storage Service)

Purpose:
To store and host my website files.

Why I chose it:
S3 is really simple to use for static websites. I can upload my site files there, and it can make them live for people to view. It's also cheap and reliable, which makes it perfect for my small buisness.

2. Amazon CloudFront (Content Delivery Network)

Purpose:
To make my website load faster for visitors anywhere, especially in Minneapolis.

Why I chose it:
CloudFront saves copies of my website closer to users, so it loads fast. Also, if something happens to S3, CloudFront can still serve cached content which adds some redundancy.

3. Amazon Route 53 (DNS)

Purpose:
To connect my website to a domain like www.dosaanddrinks.com.

Why I chose it:
Without Route 53, I'd have to share an ugly long URL. This makes it easy for people to find my website with a nice domain name.

4. AWS Certificate Manager (SSL/HTTPS)

Purpose:
To make the website secure (https instead of http).

Why I chose it:
Nobody wants to visit a website that says "Not Secure." This service gives me free SSL certificates, which helps keep my website safe and professional.

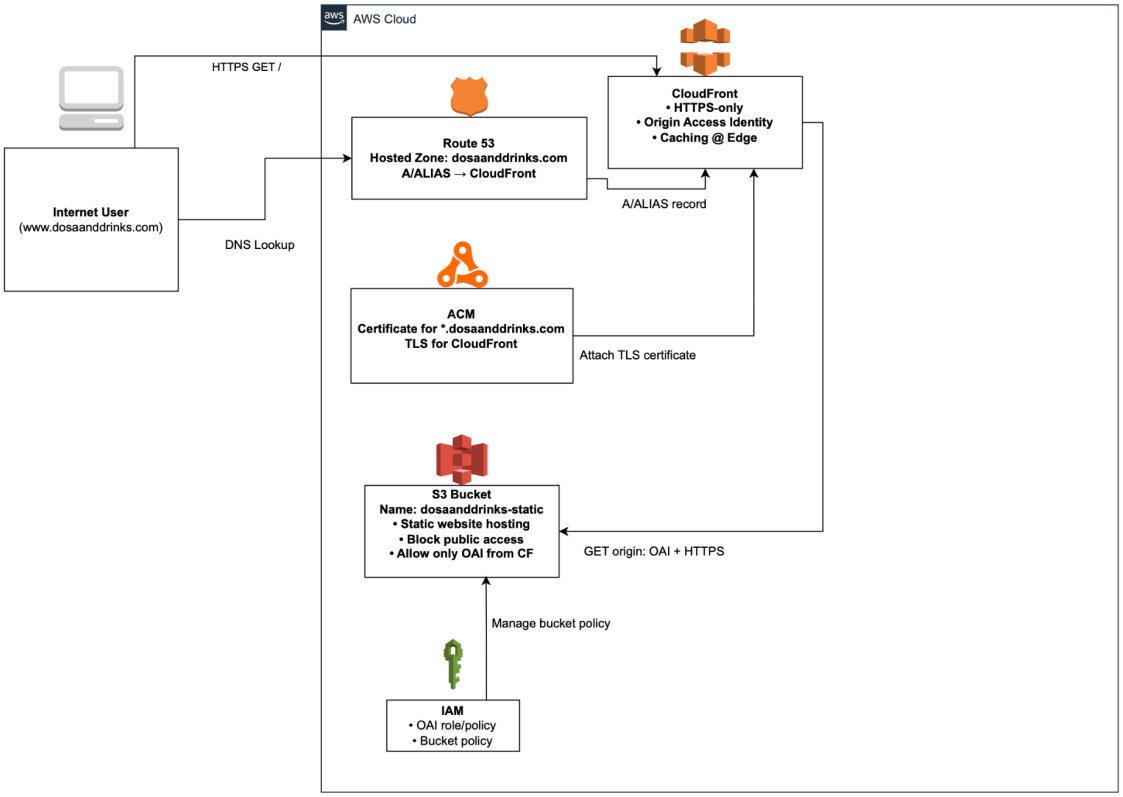

5. AWS Identity and Access Management (IAM)

Purpose:
To control who can access my website files on AWS.

Why I chose it:

I don't want anyone to randomly upload or change files on my website. IAM helps me set permissions properly and make sure only CloudFront can access the S3 files directly.

PART 3: Architecture and Design

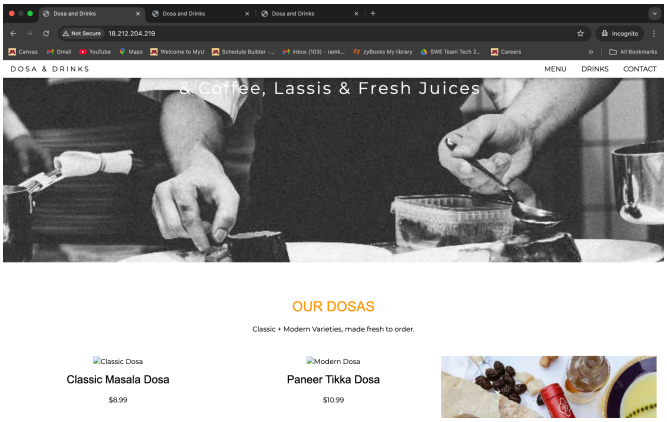

PART 4: Networking and Redundancy

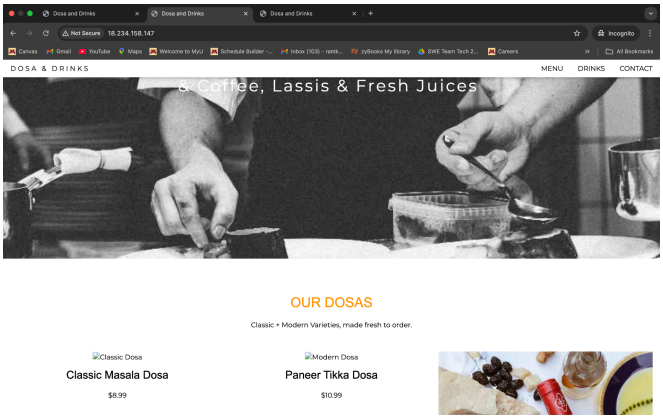

Initial ALB Test

Dosa and Drinks site loading via the Application Load Balancer (all servers up)

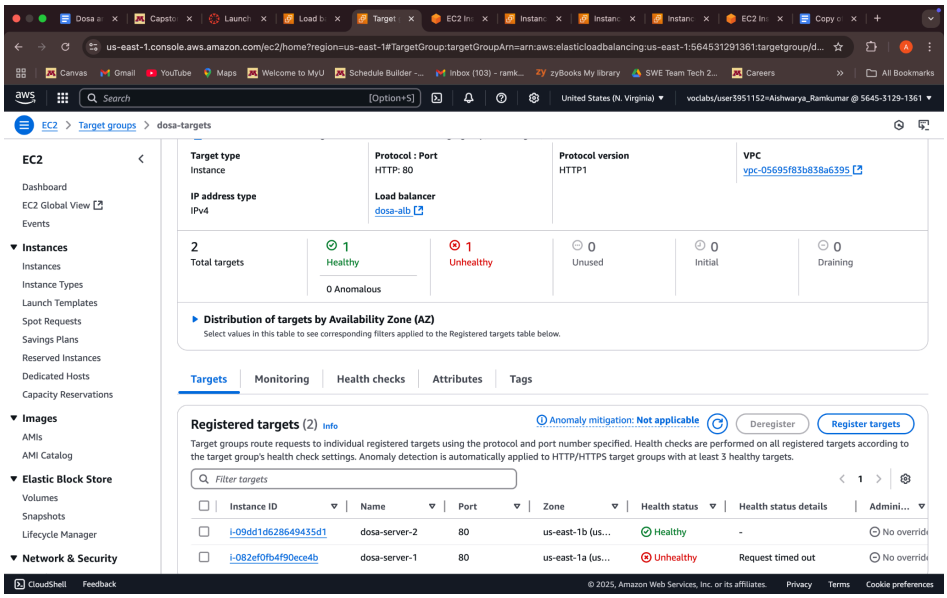

Server 1:

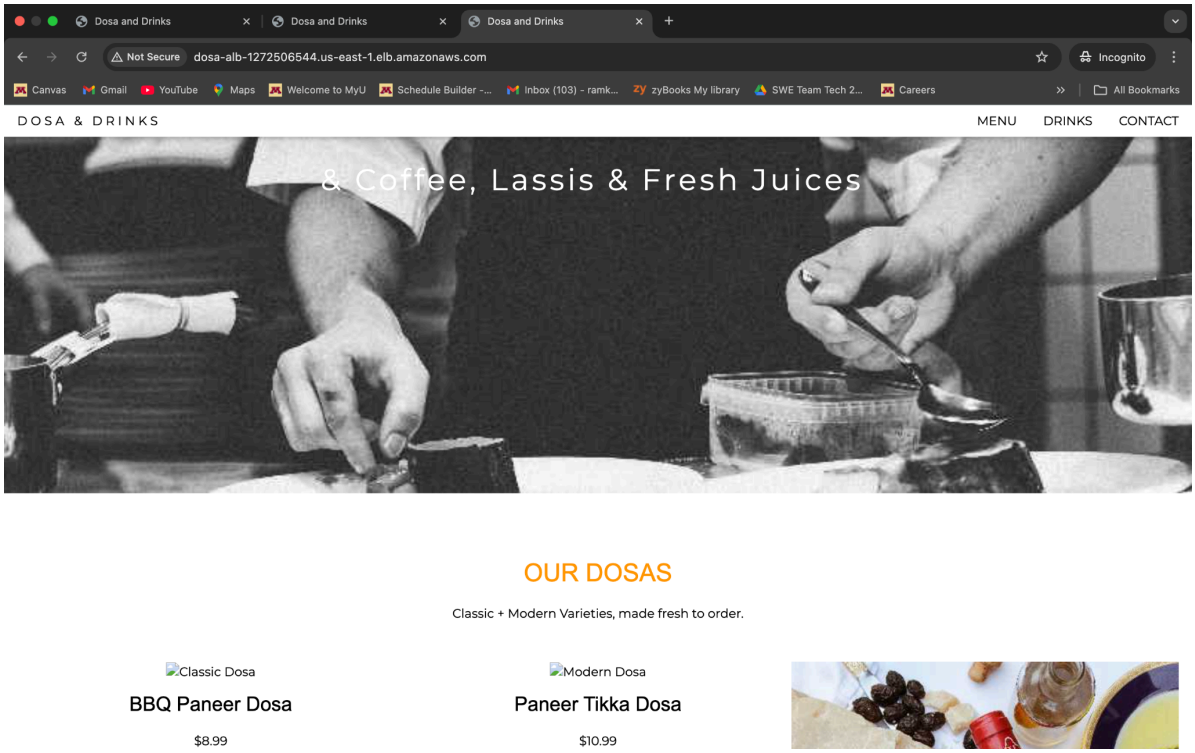

Server 2:

After stopping dosa-server-1: Target Group showing dosa-server-1 Unhealthy and dosa-server-2 Healthy

Site still live via ALB URL with only dosa-server-2 handling traffic

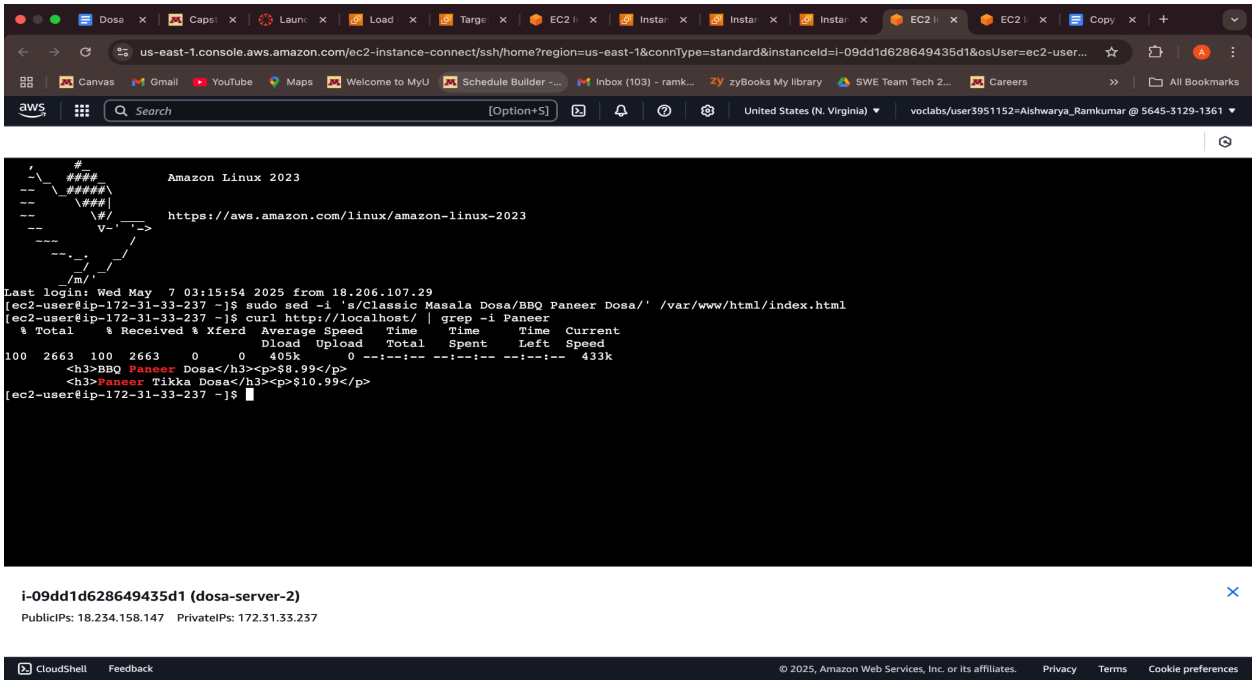

PART 5: AWS CLI or AWS Cloud Shell Interaction

I used the EC2 Instance Connect terminal right in the AWS console. Once I had my ec2-user@ prompt, I ran a single sed command to replace the menu item text in /var/www/html/index.html.

In the browser‑shell I ran:
> sudo sed -i 's/Classic Masala Dosa/BBQ Paneer Dosa/' /var/www/html/index.html
> curl http://localhost/ | grep -i Paneer

The curl confirmed the change on the server, then I loaded the ALB URL in my browser to prove the update was live.

Instance Connect shell with sed + curl output:

Browser screenshot of the updated menu item on the live site:
